Opening minds to a brighter future
Mental ill-health represents 60% of the health burden of young Australians.
Only 13% of young men and 31% of young women access the mental health care they need.

EARLY PSYCHOSES: A LIFETIME PERSPECTIVE

28/11/2016 - 01/12/2016 RAI Congress Centre, AMSTERDAM

7th INTERNATIONAL CONFERENCE ON EARLY PSYCHOSIS

The meeting will bring together the world's leading researchers in early psychosis with a focus on genetic and environmental risk and protective factors, influencing the onset and course of the illness, both biological and psychosocial research and early and long-term treatment. The meeting will be a forum for the exchange of ideas, the sharing of experiences, developing new teams of investigators and clinicians. A major focus will be the connections between early intervention and mental health care and schizophrenia.

Amsterdam, the Netherlands, is the host city for the 7th International Conference on Early Psychosis.

An educational and stimulating program will be developed around the early and late stages of psychosis and schizophrenia and will consist of plenary lectures, keynotes, seminars, poster presentations, and poster networking.

We hope you will take advantage of the great opportunities in the Netherlands in November 2016.

Introduction
Early intervention in psychotic disorders has gained momentum in the last decade, and there is now an estimated 200 centers worldwide offering specialist services for young people experiencing their first episode of psychosis.

Economic impact of early intervention in people at high risk of psychosis

1 OASIS and Department of Psychological Medicine, Institute of Psychiatry, King’s College London, UK
2 Department of Psychiatry and Neuropsychology, Maastricht University, The Netherlands
3 Centre for the Economics of Mental Health, Health Service and Population Research Department, Institute of Psychiatry, King’s College London, UK
4 Personal Social Services Research Unit, London School of Economics, UK
5 Lambeth Early Onset Service, South London and Maudsley Trust, UK

Background. Despite the increasing development of early intervention services for psychosis, little is known about their cost-effectiveness. We assessed the cost-effectiveness of Outreach and Support in South London (OASIS), a service for people with an at-risk mental state (ARMS) for psychosis.

Method. The costs of OASIS compared to care as usual (CAU) were entered in a decision model and examined for 12- and 24-month periods, using the duration of untreated psychosis (DUP) and rate of transition to psychosis as key parameters. The costs were calculated on the basis of services used following referral and the impact on employment. Sensitivity analysis was used to test the robustness of all the assumptions made in the model.

Results. Over the initial 12 months from presentation, the costs of the OASIS intervention were £1872 higher than CAU. However, after 24 months they were £961 less than CAU.

Conclusions. This model suggests that services that permit early detection of people at high risk of psychosis may be cost saving.

Cost-effectiveness of an early intervention service for people with psychosis†

Paul McCrone, Tom K. J. Craig, Paddy Power and Philippa A. Garety

Background
There is concern that delaying treatment for psychosis may have a negative impact on its long-term course. A number of countries have developed early intervention teams but there is limited evidence regarding their cost-effectiveness.

Aims
To compare the costs and cost-effectiveness of an early intervention service in London with standard care.

Method
Individuals in their first episode of psychosis (or those who had previously discontinued treatment) were recruited to the study. Clinical variables and costs were measured at baseline and then at 6- and 18-month follow-up. Information on quality of life and vocational outcomes were combined with costs to assess cost-effectiveness.

Results
A total of 144 people were randomised. Total mean costs were £11 685 in the early intervention group and £14 062 in the standard care group, with the difference not being significant (95% CI =£8128 to £3326). When costs were combined with improved vocational and quality of life outcomes it was shown that early intervention would have a very high likelihood of being cost-effective.

Conclusions
Early intervention did not increase costs and was highly likely to be cost-effective when compared with standard care.

Declaration of Interest
None.
OMEGA-3 FATTY ACIDS REDUCE THE RISK OF EARLY TRANSITION TO PSYCHOSIS IN ULTRA-HIGH RISK INDIVIDUALS
A double-blind randomized, placebo-controlled treatment study

Vocational intervention in first-episode psychosis: individual placement and support v. treatment as usual

Eóin Killackey, Henry J. Jackson and Patrick D. McGorry

Background
Unemployment is a major problem for people with first-episode psychosis and schizophrenia. This has repercussions for the economy, social functioning and illness prognosis.

Aims
To examine whether a vocational intervention – individual placement and support (IPS) – which has been found to be beneficial in populations with chronic schizophrenia, was a useful intervention for those with first-episode psychosis.

Method
A total of 41 people with first-episode psychosis were randomised to receive either 6 months of IPS + treatment as usual (TAU) (n=20) or TAU alone (n=21).

Results
The IPS group had significantly better outcomes on level of employment (13 v. 2, P<0.001), hours worked per week (median 38 v. 22.5, P=0.006), jobs acquired (23 v. 3) and longevity of employment (median 5 weeks v. 0, P=0.021). The IPS group also significantly reduced their reliance on welfare benefits.

Conclusions
Individual placement and support has good potential to address the problem of vocational outcome in people with first-episode psychosis. This has economic, social and health implications.

Early intervention for adolescents with borderline personality disorder using cognitive analytic therapy: randomised controlled trial

Andrew M. Chanen, Henry J. Jackson, Louise K. McCutcheon, Martina Jovev, Paul Dudgeon, Hok Pan Yuen, Dominic Germans, Helen Nistico, Emma McDougall, Caroline Weinstein, Verity Clarkson and Patrick D. McGorry

Background
No accepted intervention exists for borderline personality disorder presenting in adolescence.

Aims
To compare the effectiveness of up to 24 sessions of cognitive analytic therapy (CAT) or manualised good clinical care (GCC) in addition to a comprehensive service model of care.

Method
In a randomised controlled trial, CAT and GCC were compared in out-patients aged 15–18 years who fulfilled two to nine of the DSM-IV criteria for borderline personality disorder. We predicted that, compared with the GCC group, the CAT group would show greater reductions in psychopathology and parasuicidal behaviour and greater improvement in global functioning over 24 months.

Results
Eighty-six patients were randomised and 78 (CAT n=41; GCC n=37) provided follow-up data. There was no significant difference between the outcomes of the treatment groups at 24 months on the pre-chosen measures but there was some evidence that patients allocated to CAT improved more rapidly. No adverse effect was shown with either treatment.

Conclusions
Both CAT and GCC are effective in reducing externalising psychopathology in teenagers with sub-syndromal or full-syndrome bipolar personality disorder. Larger studies are required to determine the specific value of CAT in this population.

First-episode mania: a neglected priority for early intervention

Philippe Conus, Patrick D. McGorry

Objective: While first-episode (FE) psychosis has become an important field of research, FE affective psychoses, and mania in particular, have been relatively neglected. This paper summarizes current knowledge about FE mania and explores the potential for early intervention.

Method: The main computerized psychiatric literature databases were accessed.

Results: When functional as well as symptomatic variables are considered, the outcome of mania is not as good as was formerly believed, a characteristic which is already present from the first episode. Various factors (lower socio-economic status, younger age at onset of illness, poor adherence to treatment, presence of comorbidity) have been identified as possible predictors of poor outcome. The prognostic value of the presence of psychotic symptoms and their congruence to mood, as well as the diagnostic subgroup, is less well established. This literature review also reveals striking similarities between manic and schizophreniform first episodes. Poor functional outcome in a significant proportion of patients following the first episode, high risk of suicide, high prevalence of comorbid diagnoses, worse outcome with a younger age at onset and with longer delay until treatment is initiated, and finally early presence of neuro-anatomical changes, are observed in both syndromes.

Conclusions: This pattern justifies the development of early intervention strategies for FE manic patients and supports more exploratory research to identify prodromal symptoms, which might ultimately lead to even earlier focus on preventive interventions.

Key words: early intervention, first-episode, mania, outcome, psychosis.

Review Article

The proximal prodrome to first episode mania – a new target for early intervention

Objectives: Affective psychoses and bipolar disorders have been neglected in the development of early intervention strategies. This paper aims to gather current knowledge on the early phase of bipolar disorders in order to define new targets for early intervention.

Methods: Literature review based on the main computerized databases (MEDLINE, PUBMED and PSYCHLIT) and hand search of relevant literature.

Results: Based on current knowledge, it is likely that an approach aiming at the identification of impending first-episode mania is the most realistic and manageable strategy to promote earlier treatment. During the period preceding the onset of the first manic episode, patients go through a prodromal phase marked by the presence of mood fluctuation, sleep disturbance, and other symptoms such as irritability, anger, or functional impairment. Additionally, various risk factors and markers of vulnerability to bipolar disorders have been identified.

Conclusions: In the few months preceding first-episode mania, patients go through a prodromal phase (prospective prodrome) that could become an important target for early intervention. However, considering the low specificity of the symptoms observed during this phase, criteria defining high-risk profiles to first-episode mania should also include certain risk factors or markers of vulnerability. While more research is needed in high-risk groups (e.g., bipolar offspring), retrospective studies conducted in first-episode mania cohorts could provide valuable information about this critical phase of the illness.

Keywords: Bipolar disorder – early intervention – mania – prodrome

Context  Adolescent offspring of depressed parents are at markedly increased risk of developing depressive disorders. Although some smaller targeted prevention trials have found that depression risk can be reduced, these results have yet to be replicated and extended to large-scale, at-risk populations in different settings.

Objective  To determine the effects of a group cognitive behavioral (CB) prevention program compared with usual care in preventing the onset of depression.

Design, Setting, and Participants  A multicenter randomized controlled trial conducted in 4 US sites in which 316 adolescents (aged 13–17 years) offspring of parents with current or prior depressive disorders were recruited from August 2003 through February 2006. Adolescents had a past history of depression, current elevated but subdiagnostic depressive symptoms, or both. Assessments were conducted at baseline, after the 8-week intervention, and after the 6-month continuation phase.

Intervention  Adolescents were randomly assigned to the CB prevention program consisting of 8 weekly, 90-minute group sessions followed by 6 monthly continuation sessions or assigned to receive usual care alone.

Main Outcome Measure  Rate and hazard ratio (HR) of a probable or definite depressive episode (ie, depressive symptom rating score of ≥4) for at least 2 weeks as diagnosed by clinical interviewers.

Results  Through the postintervention session follow-up, the rate and HR of incident depressive episodes were lower for those in the CB prevention program than for those in usual care (2.4% vs 32.7%, HR, 0.06; 95% confidence interval [CI], 0.04–0.98). Adolescents in the CB prevention program also showed significantly greater improvement in self-rated depressive symptoms than those in usual care (mean change, −1.1 vs −2.2; P = .03). Current paternal depression at baseline moderated intervention effects (HR, 5.98; 95% CI, 2.29–16.68; P = .001). Among adolescents whose parents were not depressed at baseline, the CB prevention program was more effective in preventing onset of depression than usual care (11.7% vs 40.5%, HR, 0.24; 95% CI, 0.11–0.56), whereas for adolescents with a currently depressed parent, the CB prevention program was not more effective than usual care in preventing incident depression (31.2% vs 24.3%, HR, 1.43; 95% CI, 0.76–2.67).

Conclusion  The CB prevention program had a significant prevention effect through the 9-month follow-up period based on both clinical diagnoses and self-reported depressive symptoms, but this effect was not evident for adolescents with a currently depressed parent.

Reform direction 10.1

We propose that a youth friendly community-based service, which provides information and screening for mental disorders and sexual health, be rolled out nationally for all young Australians. The chosen model should draw on evaluations of current initiatives in this area – both service- and internet/telephonic-based models. Those young people requiring more intensive support can be referred to the appropriate primary health care service or to a mental or other specialist health service.

Reform direction 10.2

We propose that the Early Psychosis Prevention and Intervention Centre model be implemented nationally so that early intervention in psychosis becomes the norm.
